

Launch Donations

An informal round among people who already know the project. Here is exactly what happens to your money.

What this is

A donation, with **zero expectations attached**. You are not buying anything and nobody is promising you a return.

SKOOP needs liquidity to trade at all, and this is how it gets funded. What comes back is written down so the terms are identical for everyone — not because anyone is owed it. Give what you would be fine never seeing again.

Read this part twice

This is beta, and the hatch is open

SKOOP runs on PunchCard's **pilot** contracts. While the network is being tested, liquidity is recoverable: the owner wallet can withdraw it at any time, with no deadline. That is deliberate — the code is new and unaudited, and liquidity that cannot be moved cannot be rescued if something turns out to be wrong.

This applies to your share as well as the protocol's. The donor vault carries the same hatch, for the same reason: a bug that stranded your liquidity with no way to recover it would be the worse outcome. Both close the same way.

It closes when the system has proven itself. `lockLP()` is a one-way call; after it, the locker behaves identically to the production contract and the liquidity genuinely cannot be withdrawn by anyone. No date is set for that — it closes when the network has run long enough to earn it, not on a calendar.

Until then: SKOOP liquidity is not permanently locked.

You do not have to take that on trust. `evacuationOpen()` on the locker returns `true` while the hatch is open and `false` once it is shut, and the dapp reads that same function rather than asserting a state. Check it whenever you like.

What comes back

Per \$1,000 donated. Everything scales.

YOU GET	VALUE	RELEASED
SKOOP at launch price A thirtieth each day	\$250	Day 1–30
A liquidity share Your claim on the donor pool positions, held by the donor vault. Earns trading fees from day one.	\$750	Day 21–30
Total at launch price	\$1,000	100%

These figures fix the count, not the value

The dollar amounts decide **how many** SKOOP and how large a liquidity share you receive, priced at launch. After that the count is fixed and the value floats — up or down, at every point in between.

Nobody is topping anything up to keep it at \$1,000.

How the liquidity share works

The pools are Uniswap v3, where a position is a single NFT that cannot be split between people. So a **donor vault** holds one position per pool and records what each donor is owed.

When your share releases, the vault withdraws that slice and sends you the proceeds — the pair asset and SKOOP, in proportion, exactly as redeeming a pool token would. You hold a claim rather than a transferable token.

One thing this buys you: v3 keeps trading fees separate from the position itself, so **fees can be paid out while your share is still held**. Your liquidity waits; your fee income does not have to.

Where the money goes

\$1,000

Your donation

splits into –

\$250

SKOOP to you

\$750

into liquidity, across two pools

the protocol matches that \$750 with \$750 of SKOOP → \$1,500 of liquidity, split evenly –

\$750

your share, in the donor vault

\$750

protocol share, in the locker

The protocol matches your money with an equal value of SKOOP, so **every dollar in creates two dollars of liquidity at launch**. You take half of what your money created. All **\$750** goes into the pools — none is taken as working capital.

The protocol's half sits in the pilot locker and there is no plan to withdraw it. While the hatch is open that is intent rather than a guarantee — which is the whole reason `evacuationOpen()` is readable by anyone.

Two pools

Liquidity is split across a SKOOP/ETH pool and a SKOOP/USDC pool. The money is split in the same ratio as the tokens, so **both pools open at exactly the same SKOOP price** and neither is cheaper than the other on day one.

Two pools rather than one because the pools keep each other honest — when one drifts, arbitrage pulls it back and the pools collect a fee each time.

The exact weighting between them is not final — see the last section. However it lands, holding ETH-paired liquidity means **SKOOP's dollar price will move with ETH** to some degree, whatever SKOOP itself is doing.

When it releases

DAY 0 Launch

Trading opens. Nothing is released to donors yet. Your share starts earning fees immediately.

DAY 1–30 SKOOP releases

A thirtieth of your tokens each day. Claim whenever you like.

DAY 21–30 Liquidity share releases

Held for the first 20 days, then a tenth each day across the final 10.

DAY 30 Everything released

Keep the share to go on earning fees, or withdraw it for the underlying pair asset and SKOOP.

Thirty days, then it is over. The schedule exists to protect the launch window, and the launch window is the first month.

Staggering inside that month is the point. For the first 20 days barely anything can be sold — around 1% of the pools a day. The liquidity release is spread across the final 10 rather than landing at once, and that stretch is the rough one, roughly 6–11% a day.

Launch price

SKOOP has no price until it trades. The launch price is **total money in both pools ÷ 3,000,000 SKOOP** — and that 3,000,000 is fixed in the contract.

So a bigger round opens at a higher price with deeper pools, and everyone pays the same price, first donor to last.

Check it yourself

Token	SK00P PunchCard · SK00P · 6 decimals
Address	0xBa147713adF122A8Fc224e52Cb431D7919831939
Network	Base · chain id 8453
Supply	100,000,000 – fixed. No mint, no owner, no pause.
Source	Verified on BaseScan
Hatch state	evacuationOpen() on the locker – true while open, false once shut

SUPPLY	SK00P	SHARE
Customer rewards Earned at the register	45,000,000	45%
Liquidity 3,000,000 at launch, the rest in reserve	30,000,000	30%
Team 30-day cliff, then vests over 730 days	15,000,000	15%
Treasury Operations and marketing	10,000,000	10%
Total	100,000,000	100%

Constants in the deployed token contract. The supply split is fixed; the suite around it is being assembled and tested by hand.

Risks

While in beta, the owner wallet can recover the liquidity

Your liquidity share and the protocol's both sit behind one key until `lockLP()` is called. This is the largest risk on the page, it is a trust assumption rather than a contract guarantee, and no date is promised for when it ends. It is at least checkable: call `evacuationOpen()`.

SKOOP may end up worth nothing

New token, no trading history, no guaranteed demand. The launch price is set by the round, not by a market.

A liquidity share is not savings

If SKOOP falls, your share withdraws as more SKOOP and less of the pair asset than went in. Fees may not cover the difference.

You are exposed to ETH as well as SKOOP

Part of the liquidity is ETH-paired. If ETH falls it drags SKOOP's dollar price down with it, even if nothing about SKOOP has changed.

No early exit from the schedule

The contracts release on the dates above and offer no way to bring them forward, including on a falling price.

Other people will sell

Most of it can happen in the final 10 days. Expect the roughest stretch there, not at the start.

The code is new and has not been audited

It is tested, and the launch is rehearsed on-chain first. Neither removes the risk of a bug or an exploit, and the whole point of this round is that the mechanism has not run at scale before.

Not set yet

Total raise target	OPEN
Minimum donation	OPEN
Donation window	OPEN
Launch date	OPEN
ETH / USDC pool weighting	OPEN
Fees paid during the hold, or at day 30	OPEN
Donor vault contract	NOT DEPLOYED
When the hatches close (locker and vault)	WHEN TESTS PASS

Worth saying plainly, because it gets claimed a lot: **held liquidity does not create a price floor**. It holds depth, not price.
